TITLE:

The Nature of the Scale Effect in Ice and the Strength of
an Ice Cover (Priroda mashtabnogo effekta u l'da i prochnost'
ledyanogo pokrova)

PERIODICAL:

Doklady Akademii nauk SSSR, 1958, Vol 122, Nr 4: pp 570-573
(USSR)

ABSTRACT:

The scale effect in ice (and also in other materials) is characterized by the following fact: The investigation of specimens of greater dimensions gives lower values of the strength limit and vice versa. None of the hitherto suggested hypotheses concerning the nature of the scale effect agrees with the experimental results. In the bending and stretching tests at any temperatures, the breaking of the ice belongs to the type of the breaking of brittle materials. It begins at the weakest part (defect) of the lower surface of the specimen. Independently of the character of this defect, the author uses the scheme of a beam and of a specimen cut out from it. A formula is derived for the tension on the lower side of the specimen which corresponds to its break-

The Nature of the Scale Effect in Ice and the Strength of an Ice Cover

ing. In a table, the theoretically calculated values of the tensions are compared with the measured ones. Agreement is satisfactory. The scale effect in ice is caused by the simultaneous influence of a breaking mechanism and of a geometric factor. The author's explanation of the nature of the scale effect is interesting in practice, since it permits the determination of the bending strength of a natural ice cover of varying thickness on the basis of laboratory tests of thin ice plates or of small specimens. There are 4 figures and 1 table.

TITLE: Mechanical properties of ice samples

SOURCE: Leningrad. Arkticheskiy i antarkticheskiy nauchno-issledovatel'skiy institut. Problemy Arktiki i Antarktiki, no. 21, 1965, 60-65

TOPIC TAGS: solid mechanical property, temperature gradient, material deformation, sea ice

ABSTRACT: Differences between the mechanical properties of ice samples and the ice cover are discussed. The author notes the lack of similarity in crystal structure between an ice mass and small ice samples and points up differences in temperature distribution over the cross section of a sample and the ice mass from which it is taken. The investigation shows that to correct for the absence of similarity, a simulated model of an ice sample developed by the author in 1957 can be used. The temperature differences can be corrected by using a two-layer sample cut from the

surface and bottom layers of the ice cover. There is no reliable method for the determination of stresses in an ice sample when fracturing takes place and detailed studies in this direction are necessary. The hypothesis that the absolute elongation of samples of various sizes is constant needs further verification. Such phenomena as the bending of fractured surfaces, the effects of impact, relaxation time, and external and internal ice friction also require further study.

Brief Survey of the Continental Tertiary Formations of Turgay and Southwest
Siberia Vestn. AN Kaz. SSR, No 6, 1953, 71-83

According to the rhythmostratigraphic and lithochemical criteria the author subdivides the series of the continental tertiary sediments into the following four formations: 1. carbonaceous-leptochlorite (middle oligocene), down to 120 meters deep; 2. kaolinite (upper oligocene), down to 40 meters deep; 3. carbonate-sulfite (lower miocene), down to 100 meters deep; 4. carbonate (middle miocene), down to 100 meters deep. Synoptic tables are presented of the continental tertiary formations of Aralo-Turgay plains and of North Kazakhstan. (RZhGeol, No 1, 1954)

Pyrrhotine in Tertiary Oolitic Ironstones of Kazakhstan

Pyrrhotine has been established in the overwhelming majority of samples of oolitic ironstones of the Middle Oligocene age, which have been gathered in Turgay and Pavlodarsk Pri-Irtysh'ye (Nearer Irtysh). Pyrrhotine is present in ores as a brecciated clastic material in grains and fragments 0.01-0.08 mm in magnitude, the grains having irregular shape, sometimes acute angled and weakly sluiced in part, and being included in leptochlorite. The most probable source of the pyrrhotine must be considered the massifs of basic and ultrabasic rocks of the western and eastern borders of the Turgay depression. (RZhGeol, No. 5, 1955) Vestn. TITLE: Tertiary Coal Accumulation in Kazakhstan and in the
Southern Part of Western Siberia (Tretichnoye uglenako-
pleniye v Kazakhstane i na yuge Zapadnoy Sibiri)

PERIODICAL: Tr. Labor. geol. uglya AN SSSR, 1956, Nr 6, pp 489-498

ABSTRACT: Three epochs of coal accumulation are recognized in the
Tertiary rocks of Kazakhstan: Eocene, middle Oligocene,
and Miocene. In the Eocene, the Kazakh upland was a
peninsula, exposed to the sea on the southwest, west,
north, and northeast. A dry tropical climate was at
times replaced for short periods by a wet climate. In
addition to conifers, the Eocene flora contained many
evergreen xerophytic tree and scrub forms. Small depos-
its of peat accumulated in lake basins, and were subse-
quently changed to friable brown coal having the fea-

Card 1/3

tures of fusain (at Beloyarovka in the upper reaches of the Olenty). Transitions are observed from carbonaceous rocks of ferruginous types. To the southeast of the Aral region, black oil shales containing plant fragments and fish scales (found at Baykhozha) belong to this epoch. Regression of the sea from the trans-Ural and Turgay plains to the great alluvial plains along the western, northern, and eastern border of the Kazakh upland began a new cycle of coal accumulation--the middle Oligocene, especially marked in Northern Aral region, the Turgay Basin, and in Western Siberia to the Altay, inclusively. The middle Oligocene coals are petrographically variable. Dense brown coal and semidull and semibright coals predominate; lignites are comparatively rare. The spore-pollen groups of the middle Oligocene [Indrikoteriyevaya svita (series)] contain a mixed pollen of moisture-loving forms (swamp poplar, swamp cypress, and alder) and xerophytes (deciduous and evergreen). Lithologic features indicate that the middle Oligocene coal-bearing sediments are of channel, flood-plain, and dry lake origin. The coal-bearing and iron bearing deposits of Aral region , Turgay, and Northern Kazakhstan are of the same age. The climate during the middle Oligocene

Card 2/3

Tertiary Coal Accumulation in Kazakhstan (Cont.)

15-57-3-3478

stage of coal accumulation approached the subtropical, with alternations of wet and dry seasons. Except for the Altay, the accumulation of coal and iron occurred under platform conditions and the thickness of the coal layers is consequently generally less than 100 m. In the Altay the thickness increases to 170 to 200 m (Chuya Valley) and the sediments are badly crumpled. In technological properties, the middle Oligocene coals are like the coals of the Krivdo-Raychikhinsk region (Amur River region). In the lower Miocene the climate became much drier. Sapropelitic and salt-bearing sediments accumulated in several intermontane basins of the Northern Tyan'-Shan'. The scale and significance of the lower Miocene sapropel accumulations has not yet been examined fully.

PERIODICAL: Izv. AN KazSSR, ser. geol. 1956, Nr 23, pp 74-83.

ABSTRACT: The author has studied 300 samples of bones from various stratigraphic horizons, from the Neogene to the Upper Permian. The accumulation of Pb, Be, and rare earths in the bones is apparently the result of separation of these elements from waters in the initial muds and in the later soil and rock washing over the buried bones. Pb is not present in fresh bones. In insects and marine animals, Pb is found in amounts of $5 \cdot 10^{-4}$ percent. The concentration of Pb is small in all the bones and is uniform throughout all the stratigraphic horizons. This Pb in the fossil bones has accumulated by replacement of

Title : Accumulation of Some Chemical Elements in Fossil Bones of Vertebrates

Orig Pub : Dokl. AN SSSR, 1956, 108, No 6, 1113-1116

Abstract : Investigated was bone material from strata of different age (Neogene to Permian) in various areas of Eurasia. According to spectral analysis data on more than 300 specimens, it was ascertained that in an overwhelming majority of cases an appreciable accumulation takes place in Y, Ce, Be, La and Pb, which are absent in freshly ashed bones of cattle and pigs. Maximum content of these elements (in %): Y~0.600, Ce~1.390, Be~0.0125, La up to ~1, Pb up to 0.010. This enrichment is of secondary nature and is connected with intensive ion-exchange reactions at the spongy surface of bones of large specific surface. The term "osteochemy" is proposed as the designation of a new aspect in the study of fossil bones.

AUTHOR: Lavrov, V. V.

TITLE: Behavior of ice under load

PERIODICAL: Zhurnal tekhnicheskoy fiziki, v. 32, no. 1, 1962, 101-105

TEXT: Since the temperature of ice is normally not far from the melting point, certain requirements of the theory of elasticity are not fulfilled. Thus, the modulus of elasticity, determined from the deflection of an ice rod, depends on l/h , the ratio between its length thickness. If l/h rises from about 0.5 to 19, the modulus of elasticity of ice will rise from about $10 \cdot 10^3$ to $60 \cdot 10^3$ kg/cm². These results were obtained with fine-grained lumps of ice (grain size about 1 mm) at -4 to -5°C. The time from leading to rupture averaged 20 sec. The results are attributed to the fact that in ice crystals near the melting point the lattice planes are easily displaced by mechanical stresses. The modulus of elasticity is the same for specimens of like geometry. The relation

$$\sigma_2 = \sigma_1 \frac{l_1 h_2}{l_2 h_1} \sqrt{\frac{l_1}{l_2}} \text{ is given for the maximum stress for specimens of}$$

B104/B138

Behavior of ice under load

different sizes. This relation is only valid for geometrically similar, or almost similar, specimens. For geometrically dissimilar specimens, the relation reads:

$$\sigma_2 = \sigma_1 \frac{l_1 h_2 E_2}{l_2 h_1 E_1} \sqrt{\frac{l_1}{l_2}} , \text{ where } E_1 \text{ and } E_2 \text{ are the moduli of elasticity. G.}$$

M. Bartenev and L. P. Tsepkov (Zav. lab., XXVI, no. 3, 330, 1960) are mentioned. There are 3 figures, 2 tables, and 2 Soviet references.

B

TITLE: A method for fastening electrical strain gauge resistance elements to a metal frame. Class 22, No. 169161

SOURCE: Byulleten' izobreteniij i tovarnykh znakov, no. 6, 1965, 36

TOPIC TAGS: fastening method, strain gauge

ABSTRACT: This Author's Certificate introduces a method for fastening electrical strain gauge resistance elements to a metal frame by heating a polymerized adhesive layer. Effective polymerization of the adhesive composition on the side adjacent to the metal frame is provided by making the device in the form of nichrome springs in a flat metal housing coated with an organosilicon insulating substance. There is a central opening in this housing which corresponds to the area where the element is to be attached when the unit is fastened to the metal frame.

ASSOCIATION: none

TITLE: On the problem of determination of beryllium in phosphate form in
the presence of titanium and other elements

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 2, 1962, 8, abstract 2K38
(V sb. "Khim., fiz.-khim. i spektr. metody issled. rud redk. i
rasseyan. elementov". Moscow, Gosgeoltekhnizdat, 1961, 19-24)

TEXT: The separation of 30.7 mg BeO with an error of ~1% (relatively)
in the presence of (in mg) Al₂O₃ (?), Fe₂O₃ 60, Cr₂O₃ 10 is performed with
ammonia, adding at the first precipitation 5 ml of 20% (NH₄)₃PO₄ solution and
10 ml of 15% solution of trilon B. The precipitate washed with 2% NH₄NO₃
solution is dissolved in HCl, and at the second precipitation 2 ml of phosphate
solution and 5 ml of trilon B solution are added. At this stage Ti interferes
with the determination of Be. To eliminate the effect of Ti, the solution,
after a preliminary neutralization of the excessive acid, is cooled, 5 ml of
20% (NH₄)₃PO₄ solution, 15 ml of 15% trilon B solution and 1 ml of perhydrol
are added and the whole is neutralized by methyl red. The separated amorphous

Abstract : Polyvaccine (P) was tested on volunteers and the reaction
was taken into account with respect to rise in temperature
and to general condition at different times. The reaction
begins to appear in 5-6 hours and reaches its maximum in
10-12 hours; after 24 hours the reaction effect wanes.
Most sensitive are persons 17-25 years old. Infiltrates
at the spot of injection of P appeared after 48-72 hours
and continued for 2 weeks. An increase in reactivity

TITLE: An investigation of certain factors that influence the development of ionising processes in the dielectric of paper-oil capacitors

PERIODICAL: Referativnyy zhurnal, Elektrotehnika i energetika, no.4, 1962, 7, abstract 4 B27. (Izv. N.-i. in-ta postoyan. toka, no.7, 1961, 231-241)

TEXT: The intensity of ionisation was assessed by measuring the rate of impulses (discharges). A schematic diagram of the equipment is given. To investigate the relationship between the intensity of ionisation and the field strength the latter was raised in steps of 2.5 kV/mm with a delay of 60 sec at each step. The experimental capacitors were of the following characteristics. Paper - type KOH-II (KON-II), thickness 10 microns and width 60 mm; number of layers 4, 5, 6 and 8; capacitance about 0.1 microfarads; impregnated with capacitor oil. The mean electrical

Card 1/2

characteristics were; $\tan \delta \approx 0.0033$; $RC \approx 8000$ megohmmicrofarads. The a.c. ionisation inception stress was studied as a function of internal pressure in the container, dielectric thickness, temperature and amount of overlap. The intensity of ionisation was also studied as a function of temperature and time of application of voltage with direct voltage, and in this case the stress was raised in steps of 10 kV/mm with a delay of 90 sec at each step. It was shown that the method of assessing the intensity of ionisation from the discharge rate is particularly useful in studying ionisation effects with direct voltage. A comparison was made between the intensity of ionisation with rising and with falling voltage for capacitors impregnated with oil and pentachlordiphenyl. In the latter case there was much less difference between the curves for rising and falling voltage than has been described in the literature.
